The Dark Side of Bank Wholesale Funding

Rocco Huang    Lev Ratnovski

May 2010*

Abstract

Banks increasingly use short-term wholesale funds to supplement traditional retail deposits. Existing literature mainly points to the "bright side" of wholesale funding: sophisticated financiers can monitor banks, disciplining bad but refinancing good ones. This paper models a "dark side" of wholesale funding. In an environment with a costless but noisy public signal on bank project quality, short-term wholesale financiers have lower incentives to conduct costly private information acquisition, and instead may withdraw based on negative public signals, triggering inefficient liquidations. Comparative statics suggest that such distortions are greater when bank assets are arm's length and tradable (corresponding to more relevant public signals and lower liquidation costs).

1 Introduction

Banks increasingly borrow short-term wholesale funds to supplement retail deposits (Feldman and Schmidt, 2001). They tap into wholesale money markets to attract cash surpluses from nonfinancial corporations, households (via money market mutual funds), other financial institutions, etc. Wholesale funds are usually raised on a short-term rollover basis with instruments such as large-denomination certificates of deposits, brokered deposits, repurchase agreements, Fed funds, and commercial paper.

The existing literature mainly points to the "bright side" of wholesale funding: exploiting valuable investment opportunities without being constrained by the local deposit supply, the ability of wholesale financiers to provide market discipline (Calomiris, 1999) and to refinance unexpected retail withdrawals (Goodfriend and King, 1998). However, some of these benefits were not realized in the recent banking crisis, revealing a "dark side" of wholesale funding (Acharya et al., 2008; Huang and Ratnovski, 2009).

This paper attempts to reconcile the traditional view on the virtues of wholesale funding with recent experiences. The key insight we suggest is that wholesale funding is beneficial when informed, but may lead to inefficient liquidations when uninformed. Formally, we consider a bank that finances a risky long-term project with two sources of funds: retail deposits and wholesale funds. Retail deposits are sluggish, insensitive to risks (partly because they are insured), and provide a stable source of long-term funding. Wholesale funds are relatively sophisticated, since their providers have the capacity to acquire information on the quality of bank projects. However, these funds are short term. Specifically, they are supplied on a rollover basis and have to be refinanced before final returns are realized, or the bank is forced into liquidation.

---

1 The "sluggishness" of retail deposits is a well-established stylized fact (Feldman and Schmidt, 2001; Song and Thakor, 2007). Retail deposits are typically insured by the government. Their withdrawals are motivated mostly by individual depositors’ liquidity needs and thus are predictable based on the law of large numbers. Another reason for "sluggishness" is the high switching costs associated with transaction services that retail depositors receive from the banks (Kim et al., 2003; Sharpe, 1990, 1997). As a result, although some accounts are formally demandable, retail deposits provide a relatively stable source of long-term funds for banks. However, the local retail deposit base is quasi-fixed in size, since it is usually prohibitively expensive to expand in the medium term (Billett and Garfinkel, 2004; Flannery, 1982).
Our modelling approach builds on Calomiris and Kahn (1991, hereafter CK), which we take as a benchmark of the “bright side” of wholesale funding. CK show that "sophisticated" wholesale financiers add value through their capacity to monitor banks and impose market discipline (force liquidations) on loss-making ones. Moreover, they show that monitoring incentives of wholesale financiers are maximized when they are senior at the refinancing stage, because it allows them to internalize the benefits of monitoring (resulting from their high share in the early liquidation payoff).

In practice, short-term wholesale funds indeed enjoy de facto (effective) seniority because of the sequential service constraint and the relative sluggishness of insured retail depositors. This was the main reason why in almost all recent bank failures (e.g., Continental Illinois, Northern Rock, IndyMac), short-term wholesale financiers were able to exit ahead of retail depositors without incurring significant losses. Interestingly, the well-publicized retail depositor run on Northern Rock took place only after the bank had nearly exhausted its liquid assets to pay off the exit of short-term wholesale funds (Shin, 2008; Yorulmazer, 2008).²

We then introduce into the benchmark CK model a novel feature: a costless but noisy public signal on the quality of bank projects. Examples of such a signal include market prices or credit ratings of traded assets (e.g., mortgage-backed securities), performance of comparable banks, market- or sector-wide indicators (e.g., house price), and bank stock prices. Wholesale financiers may use the public signal when costly private monitoring fails to produce precise information on bank fundamentals (because of either low investment in monitoring or merely bad luck).

We show that this minor and plausible change to the CK setup can, under some conditions, lead to outcomes consistent with the "dark side" of wholesale funding seen in the recent banking crisis. The incentives of wholesale financiers to liquidate based on

²Marino and Bennett (1999) analyze six major bank failures in the US between 1984 and 1992 and find that uninsured large deposits fell significantly relative to small insured deposits prior to failures. During the New England banking crisis, failing banks experienced a 70 percent decline in uninsured deposits in their final two years of operation while being able to raise insured deposits to replace the outflow. Billett et al. (1998) also find that banks typically raised their use of insured deposits vis-a-vis wholesale deposits after being downgraded by Moody’s.
noisy information can be too high compared to the socially optimal levels, particularly when they are senior claimants to the liquidation value. The reason is that senior wholesale financiers can obtain a disproportionately large share of the liquidation value of assets, at the expense of providers of long-term funds such as passive core depositors. When wholesale financiers anticipate a high likelihood of an early liquidation with a safe exit, they become less interested in acquiring costly private information on bank project quality in the first place.

Therefore, in the presence of a noisy public signal, higher seniority of short-term wholesale funds has two effects. One, in line with CK, is the positive effect that rewards them for monitoring and market discipline efforts. Another, a novel one, is the negative effect that reduces their private cost of liquidating banks based on noisy information. The socially optimal seniority of short-term wholesale funds must trade off the two offsetting effects. We find that welfare is maximized at an intermediate level of seniority. While the monitoring incentives of wholesale financiers increase in seniority for low values of seniority (the CK effect), they decrease for higher values of seniority so that higher seniority translates purely into more liquidations. Deviations from that interior optimum to either side result in less monitoring and possibly more inefficient liquidations. This result contrasts with the CK benchmark in which higher seniority for the sophisticated funds is always better.

Our results also reveal that the incentives of short-term financiers to liquidate banks based on a noisy negative signal are higher when the signal is more precise, yet not as precise as to make liquidation decisions based on it socially optimal, that is, when the signal has an intermediate level of precision. The precision of the noisy public signal (i.e., the probability that it is correct) can be interpreted as the availability of relevant public signals on individual bank performance. In a bank cross-section, these predictions suggest that the use of senior short-term funds is beneficial in "traditional" banks that hold mainly opaque and nontradable relationship loans, consistent with the "bright side" predictions of CK. Yet the "dark side" effects are likely to play a role in "modern" banks with large exposures to standardized and tradable arm’s length assets.
with readily available public information.

The rest of the paper is structured as follows. Section 2 sets up the benchmark CK-type model of the "bright side" of wholesale bank funding. Section 3 introduces the costless but noisy signal on bank project quality and analyzes the "dark side" of wholesale funding. Section 4 discusses the model's limitations and implications. Section 5 concludes.

2 The Bright Side of Wholesale Funding

2.1 Model

We start by outlining a version of the Calomiris and Kahn (1991) model, which we use to describe a benchmark "bright side" of bank wholesale funding. In this version, the economy consists of a bank (with access to an investment project) and two types of financiers: retail and wholesale. There are three dates (0, 1, 2), no discounting, and everyone is risk-neutral.

The project A bank has exclusive access to a profitable but risky long-term project. For each unit invested at date 0, at date 2 the project returns $X$ with probability $p$ or 0 with probability $1 - p$, with a positive net present value: $Xp > 1$. The project may also be liquidated at date 1 returning $L < 1$ per unit initially invested. The maximum investment size is 1.

Funding The bank has no initial capital and needs to borrow in order to invest. There are two types of financiers:

1. The "retail depositors" are unsophisticated, passive, and scarce. They never get advance information on date 2 project realization, and never withdraw before date 2, providing a bank with a source of stable long-term (yet formally demandable)
funds. The interest rate payable on retail deposits (date 0 to date 2) is risk-insensitive and fixed at \( R_D: 1 \leq R_D < pX \). The bank is endowed with a fixed deposit base of \( D < 1 \) and it is prohibitively costly to expand it within the horizon of the model.

2. The "wholesale financier" is sophisticated, has an unlimited supply of funds, but is short-term. He can choose to monitor the bank before date 1 and use obtained information to decide whether to refinance or liquidate the bank at date 1.

The wholesale financier can lend to the bank any amount at date 0 against real expected return \( \rho \), which reflects his alternative return on funds. The bank’s project is better than alternative investment opportunities so initial funding is always available: \( 1 \leq \rho < pX \). The amount of wholesale funds attracted by the bank is denoted \( W \). Since the maximum investment size is 1, \( W \leq 1 - D \).

Wholesale funding needs to be refinanced at date 1. If the wholesale financier refuses to roll over, the bank is forced into liquidation. The endogenous interest rate on wholesale funds is denoted \( R \). We assume that \( R \) is set from date 0 to date 2. This allows us to avoid hold-up by the wholesale financier at date 1 (cf. von Thadden, 1995).

We model the wholesale financiers as a single agent, abstracting from competition and coordination problems among multiple wholesale financiers (see Diamond and Dybvig, 1983; Rochet and Vives, 2004; and Von Thadden, 2004; for examples of analysis of such problems).

**Monitoring**  The wholesale financier can obtain advance information on the project’s date 2 realization by monitoring the bank between dates 0 and 1. He chooses the intensity of monitoring \( m \) (\( 0 \leq m < 1 \)), and incurs corresponding cost \( C(m) \) \((C(0) = 0, C(1) = \infty, C'(0) = 0, C''(m) > 0, C''(m) > 0)\). The wholesale financier then receives *precise* information of date 2 realization with probability \( m \). He receives no information at all with probability \( 1 - m \), in which case he knows that monitoring has failed.
Liquidation and creditor seniority If the wholesale financier refuses to roll over initial funding at date 1, the bank is liquidated. Since $L < 1$, all creditors cannot be repaid in full. The division of liquidation value $L(D + W)$ among them is governed by seniority rules. The relative seniority of the wholesale financier versus retail depositors is described by the share $s$ ($0 \leq s \leq 1$) of the liquidation value received by the wholesale financier.

To keep the model tractable, we assume that the amount of wholesale funding attracted by the bank is not insignificant compared to the liquidation value:

$$pW > L$$ (1)

This ensures that $pWR > sL(D+W)$, so that the wholesale financier never liquidates a bank based solely on a prior $p$ (to receive $L(D+W)$ rather than wait for $pWR$ expected at date 2), capturing the stylized fact that "no news is good news" and bank runs are uncommon absent negative information.

For determinacy, we assume that all agents prefer bank continuation to liquidation when they are otherwise indifferent between the two options. This implies, in particular, that the bank always prefers continuation, since it receives nothing in liquidation, and that date 1 liquidations can be triggered only by the wholesale financier.

The benchmark analysis proceeds in three steps. We start with the basic case of retail deposit funding. We then show the positive effects of wholesale funds: expanding investment beyond the constraints of the fixed depositor base, and monitoring that gives rise to market discipline. Finally, we verify that the equilibrium private choices of the bank and the wholesale financier are the socially optimal ones.

2.2 Retail deposits only

Consider a bank funded by retail deposits only. Its volume of initial investment $D$ is lower than the maximum possible investment size of 1; such spare capacity is inefficient,
because the bank’s project has a positive net present value. Furthermore, the bank always continues until date 2: the bank prefers continuation, while retail depositors are uninformed and passive. This means that bad projects are not terminated at date 1 (to preserve liquidation value $L$) but continue until date 2, returning 0. This is the second source of inefficiency. The monetary value of social welfare when the bank is financed with retail deposits only is:

$$\Pi_{Dep} = D(pX - 1) \quad (2)$$

### 2.3 Wholesale funds: Welfare maximization

Now consider a bank that also uses $W$ of wholesale funds. In this section, we derive the socially optimal monitoring and continuation decisions of the wholesale financier and the amount of wholesale funds attracted by a bank.

Consider first the continuation decision. If monitoring produces precise, advance information on date 2 project return, a good bank should be refinanced at date 1 ($X > L$) while a bad one should be liquidated ($L > 0$). When monitoring yields no information, so that project quality is unknown, a bank should be refinanced, since $Xp > L$.

The optimal intensity of monitoring, $m^*$, and the optimal use of wholesale funds, $W^*$, are obtained by maximizing the monetary value of social welfare:

$$\Pi = (D + W) (pX + m(1 - p)L - 1) - C(m) \quad (3)$$

This yields the maximum possible amount of wholesale funds, so that the complete initial investment 1 is undertaken:

$$W^* = 1 - D$$

and $m^*$ given by:

$$C'(m^*) = (1 - p)L \quad (4)$$
Comparing (2) and (3) highlights the beneficial effects of the use of wholesale funds: higher investment volume \( D + W = 1 \) instead of \( D \), and preservation of the liquidation value of some bad banks \( m^*(1 - p)L \) at the cost of monitoring \( C(m^*) \).

2.4 Wholesale funds: Private equilibrium

We now study private choices of the bank and the wholesale financier, and compare the choices with the social optimum.

**Wholesale financier** Between dates 0 and date 1, the wholesale financier chooses monitoring intensity, and he learns the outcome of his monitoring. Then at date 1 he chooses whether to refinance or liquidate the bank.

His continuation decision is in line with the social optimum: when monitoring yields precise information on project quality, the wholesale financier has incentives to refinance a good bank \( (WR > sL(D + W)) \) and liquidate a bad one \( (sL(D + W) > 0) \). When monitoring yields no information, the wholesale financier rolls over funding, since, by (1), \( pWR > sL(D + W) \).

In choosing the intensity of monitoring \( m \), the financier maximizes:

\[
\Pi^W = pWR + m(1 - p)sL(D + W) - C(m)
\]

which obtains the private choice of \( m^W \), given by:

\[
C'(m^W) = (1 - p)sL(D + W)
\]

Observe from (4) and (5) that \( m^W = m^* \) for \( s = 1 \) and \( D + W = 1 \). This means that the wholesale financier chooses the optimal intensity of monitoring when he is a senior creditor at date 1 and the amount of wholesale funding is the maximum possible. The intuition is that high seniority and high volume allow him to fully internalize the benefits of monitoring: his payoff in monitoring-enabled liquidations \( sL(D + W) \) is increasing in
seniority and the volume of wholesale funds.

**Bank**  The bank makes decisions on the amount of wholesale funds \( W \) and the funds’ creditor seniority \( s \). The bank’s surplus is:

\[
\Pi^B = p[D(X - R_D) + W(X - R)]
\]  

(6)

The interest rate \( R \) demanded by the wholesale financier, obtained from the zero-profit condition, is:

\[
R = \frac{W_p + C(mW) - mW(1 - p)sL(D + W)}{Wp}
\]  

(7)

**Lemma 1** \( \Pi^B \) increases in \( s \) and \( W \) and hence is maximized for \( W = 1 - D = W^* \) and \( s = 1 = s^* \), consistent with the social optimum.

**Proof.** See Appendix.  ■

The intuition is that \( \Pi^B \) increases in \( s \) because \( R \) decreases in \( s \): when the wholesale financier receives more in early liquidations, he requires lower compensation for bearing risks. \( \Pi^B \) increases in \( W \) because with a higher amount of wholesale funds, the bank is able to invest more and the per-unit cost of monitoring declines. We can summarize the benchmark result in Proposition 1:

**Proposition 1** In the benchmark "bright side" case, the bank’s decisions on the amount and the creditor seniority of wholesale funds, as well as the wholesale financier’s decisions on monitoring and continuation, are all socially optimal. The outcome is \( W = W^* \), \( s = s^* \), \( m = m^* \), and only banks known by the wholesale financier to be bad ones are liquidated.
3 The Dark Side of Wholesale Funding

We now turn to the analysis of the "dark side" of bank wholesale funding. In this section we show how a plausible change to the "bright side" CK-style setup of Section 2 can significantly alter its results.

We introduce an additional source of information: a free but noisy signal on date 2 project realization, which the wholesale financier receives prior to date 1 but after he has made a decision on the intensity of his monitoring. The wholesale financier can use this signal when his monitoring yields no information (either because of low intensity of monitoring or merely bad luck). Although the signal is free, it is complex, and therefore not received by retail depositors.

We specify the signal to have the same distribution of outcomes as that of the underlying project. It takes two values: "positive" or "negative" and is characterized by a precision parameter \( \theta \) (\( 0 \leq \theta \leq 1; \theta = 0 \) for complete noise and \( \theta = 1 \) for completely precise information). The probability of receiving a positive signal is \( p \) (the same as that for \( X \) at date 2). Conditional on this, the probability of getting \( X \) at date 2 is \[ p + \theta(1 - p) \], and that of getting 0 is \[ (1 - p) - \theta(1 - p) \]. The probability of a negative signal is \( 1 - p \). Conditional on this, the probability of getting \( X \) at date 2 is \[ p - \theta p \], and that of getting 0 is \[ (1 - p) + \theta p \].

We show that such a relatively minor twist can generate outcomes contrasting to those of the CK-style setup. Previously, the wholesale financiers always refinance the bank at date 1 if his private monitoring yields no information. That is consistent with both his private incentives and welfare maximization. Now with the introduction of the signal described above, the wholesale financier has lower incentives to monitor and excess incentives to liquidate the bank based on noisy public information.

3.1 Welfare maximization

We start by outlining the benchmark socially optimal decisions on monitoring, refinancing, and the use of wholesale funds in the presence of a free but noisy signal on bank
Refinancing at date 1  When the wholesale financier’s private monitoring before date 1 produces precise information on project quality, the noisy public signal revealed afterwards (also before date 1) cannot add information. As before, good banks will be refinanced and bad ones, liquidated.

Without the noisy signal, continuation at date 1 is always optimal when private monitoring produces no information on project quality. The noisy signal refines date 1 expectations of date 2 project outcome. When a noisy signal is positive, the posterior of project success at date 2 increases to \( p + \theta(1 - p) \), so it naturally remains optimal that the bank is refinanced at date 1. However, when a noisy signal is negative, the posterior of project success at date 2 falls to \([p - \theta p]pX \geq L\), it remains optimal to refinance the bank. However, if precision is high enough so that \([p - \theta p]pX < L\), it becomes socially optimal to liquidate the bank based solely on a noisy signal. The threshold value of \( \theta \) is:

\[
\theta^* = 1 - \frac{L}{p^2X} \tag{8}
\]

Monitoring  Now consider how the noisy signal affects the optimal intensity of monitoring and the amount of wholesale funding. Recall that, when the precision of the signal is low, \( \theta \leq \theta^* \), it is optimal to disregard it. The maximization problem is the same as in the benchmark case given in (3); the optimal amount of wholesale funding is \( W^* = 1 - D \) and optimal monitoring is \( m^* \) given in (4).

When the precision of the noisy signal is high, \( \theta > \theta^* \), it is optimal to use it and liquidate the bank when the signal is negative. The monetary value of social welfare is:

\[
\Pi_{Liq} = (D + W)(m[pX + (1 - p)L] + (1 - m)[p[p + \theta(1 - p)]X + (1 - p)L] - 1) - C(m) \tag{9}
\]
The term \( m [pX + (1 - p)L] \) reflects the payoff from private monitoring that produces precise information on project quality. The term \((1-m) [p [p + \theta(1 - p)] X + (1 - p)L]\) is novel. It represents the payoff from using the noisy signal when private monitoring produces no information (and liquidating the bank upon a negative signal): \( p \) is the probability of a positive signal conditional on which the bank is refinanced and yields \( X \) with probability \( [p + \theta(1 - p)] \); \((1 - p)\) is the probability of a negative signal conditional on which the bank is liquidated to preserve \( L \).

As before, the social welfare (9) is increasing in \( W \), so that it is optimal to use as much wholesale funding as possible: \( W_{Liq}^* = 1 - D = W^* \). The optimal intensity of monitoring \( m_{Liq}^* \) is given by:

\[
C'(m_{Liq}^*) = p(1 - p)(1 - \theta)X
\]  

(10)

Observe that \( m_{Liq}^* < m^* \). This is easy to verify by applying the condition for using the noisy signal \([p - \theta p] pX < L\) to (4) and (10). The intuition is that the availability of a free but noisy signal makes the private information obtained through costly monitoring less valuable.

3.2 Incentives of the wholesale financier

Now consider private choices of the wholesale financier.

Inefficient liquidations As before, when monitoring yields precise information on the quality of the bank project, the wholesale financier has incentives to follow its outcome: refinance known good banks and force liquidation of known bad ones. When monitoring fails to yield information, the uninformed wholesale financier can now use the noisy public signal. Conditional on a negative signal, his expected continuation payoff is \([p - \theta p] WR\) and his liquidation payoff is \( sL(D + W)\). For the wholesale financier, it
is privately optimal to follow a noisy signal and liquidate the bank for:

\[ sL(D + W) > [1 - \theta] pWR \]  

(11)

Expression (11) can be interpreted either as sufficiently high precision of the noisy signal:

\[ \theta > \theta^W = 1 - \frac{sL(D + W)}{pWR} \]  

(12)

or as sufficiently high creditor seniority for the wholesale financier:

\[ s > s^W = \frac{(1 - \theta) pWR}{L(D + W)} \]  

(13)

Note that the incentives of the wholesale financier to liquidate the bank increase in \( s \). He has no incentives for early liquidations when junior \( (\theta^W_{s=0} = 1) \), but may have excessive incentives to liquidate when senior \( (\theta^W_{s=1} < \theta^*) \).

**Monitoring** Consider the monitoring choices of the wholesale financier. When he is sufficiently junior, \( s \leq s^W \), he disregards the noisy signal, so his private choice of monitoring intensity is the same as the benchmark \( m^W \) given in (5).

However, when he is sufficiently senior, \( s > s^W \), he has incentives to use the noisy signal and liquidate the bank when the signal is negative. Then, in choosing monitoring intensity, he maximizes:

\[
\Pi^W = m \left[pWR + (1 - p)sL(D + W)] + (1 - m)[p[p + \theta(1 - p)]WR + (1 - p)sL(D + W)] - C(m) \right]
\]

(14)

which obtains:

\[
C'(m^W_{Liq}) = p(1 - p)(1 - \theta)WR_{Liq}
\]

(15)

Observe that, unlike for \( m^W \) given in (5), \( s \) does not enter directly into the specification of \( m^W_{Liq} \) given in (15). Rather, it affects \( m^W_{Liq} \) indirectly through \( R_{Liq} \). To see
that, consider the interest rate charged by the wholesale financier:

\[ R_{Liq} = \frac{W \rho + C(m_{Liq}^W) - (1 - p)sL(D + W)}{m_{Liq}^W Wp + (1 - m_{Liq}^W)[p + \theta(1 - p)]Wp} \]  

(16)

As \( s \) increases and the wholesale financier receives more in date 1 liquidations, he requires a lower compensation at date 2; hence \( R_{Liq} \) decreases in \( s \). And since \( m_{Liq}^W \) increases in \( R_{Liq} \), it decreases in \( s \). The contrasting effects of creditor seniority on the behavior of the wholesale financier with and without a noisy public signal are illustrated in Figure 1. Therefore, \( s = s^W \) is a threshold point not only for the liquidation decision but also for the choice of monitoring intensity.

**Lemma 2** Consider \( s^W \), the threshold point for the wholesale financier’s use of the noisy public signal, given by (11).

1. \( s^W \) decreases in \( \theta \) and \( L \); it decreases in \( D \) and increases in \( W \) (provided that \( D + W = 1 \)).

2. For \( s \leq s^W \), the wholesale financier never liquidates a bank based on a noisy signal and the intensity of his monitoring increases in his creditor seniority: \( \partial m^W / \partial s > 0 \).

3. For \( s > s^W \), the uninformed wholesale financier chooses to liquidate a bank following a negative noisy signal and the intensity of his monitoring decreases in seniority: \( \partial m_{Liq}^W / \partial s < 0 \).

4. Monitoring and interest rate functions are continuous at \( s^W \): \( m_{s=s^W}^W = m_{Liq,s=s^W}^W \) and \( R_{s=s^W} = R_{Liq,s=s^W} \)

**Proof.** See Appendix.  

**Optimal seniority of wholesale funds** Based on the incentives of the wholesale financier identified in Lemma 2, we can now formulate the result on the socially optimal seniority and use of wholesale funds.

**Proposition 2** Consider the case with possible welfare-reducing liquidations: \( \theta_{s=1}^W < \)
\( \theta \leq \theta^* \). The socially optimal creditor seniority of the wholesale financier is \( s = s^W \) given in (13), \( s^W < 1 \). Setting \( s = s^W \) aligns the continuation decision of the wholesale financier with the social optimum, and there are no inefficient liquidations. It also maximizes the intensity of monitoring, albeit at a level below the social optimum: \( m^W(s^W) < m^* \). All else equal, the incentives of the wholesale financier for inefficient liquidations are higher, and hence the socially optimal seniority of wholesale funding is lower when the precision of the public signal \( \theta \) is higher, the bank’s liquidation value \( L \) is higher, and there are more deposits \( D \) serving as buffer for short-term funds’ exit.

Point \( s^W \) can be thought of as the highest seniority consistent with the "bright side" of wholesale funding. For \( s > s^W \), the wholesale financier becomes sufficiently senior to undertake inefficient liquidations of banks based on overly noisy public information, and higher seniority leads to lower monitoring.

### 3.3 Incentives of the bank

The previous section has established the socially optimal seniority of the wholesale financier: an intermediate \( s^W \). However, in practice the decision on creditor seniority \( s \) is taken by a bank with the objective of maximizing its private surplus. We now study the bank’s choice of creditor seniority and show that it can deviate from the social optimum.

**The bank’s choice of creditor seniority for the wholesale financier** The bank has no incentives to assign creditor seniority below the socially optimal level, because for \( s < s^W \) its surplus given in (6) increases in \( s \).

Consider, however, the private incentives for the bank to assign too high creditor seniority, \( s > s^W \). The bank’s cost is similar to the social one: losses when good projects are abandoned in inefficient liquidations. However, the bank also has a private benefit: offering the wholesale financier higher seniority reduces the interest rate \( R \). Since the interest rate on deposits \( R_D \) is fixed, this leads to an increase in the bank’s surplus. If
the net effect is positive (lower interest expense compensates the higher risk of inefficient liquidations), the bank has private incentives to offer too high seniority.

Indeed, recall that the bank’s surplus at \( s^W \) is:

\[
\Pi_{s=s^W}^B = p \left[ D(X - R_D) + W(X - R_{s=s^W}) \right]
\]  
(17)

with \( R \) given by (7).

The bank’s surplus for \( s > s^W \) is:

\[
\Pi_{Liq}^B = \left[ p - (1 - m_{Liq}^W)p(1 - \theta)(1 - p) \right] \left[ D(X - R_D) + W(X - R_{Liq}) \right]
\]  
(18)

with \( R_{Liq} \) given by (16). (Note immediately that \( \Pi_{Liq}^B \) increases in \( W \), so that the bank chooses socially optimal \( W = 1 - D \).)

It is instructive to compare the two expressions above. Observe that in \( \Pi_{Liq}^B \) the first multiplicative term features a lower probability of bank project success than that in \( \Pi_{s=s^W}^B \); the difference is the probability \( (1 - m_{Liq}^W)p(1 - \theta)(1 - p) \) of inefficient liquidations. The second term – the bank’s surplus conditional on project success, at the same time, is higher in \( \Pi_{Liq}^B \) than in \( \Pi_{s=s^W}^B \), since \( R_{Liq} < R_{s=s^W} \) due to higher \( s \).

Consider the bank’s surplus as a function of \( s \). Early liquidations trigger a discrete drop in \( \Pi^B \) at \( s^W \). The value of that decline is:

\[
\Pi_{s=s^W}^B - \Pi_{Liq,s=s^W}^B = (1 - m_{Liq}^W)p(1 - \theta)(1 - p) \left[ D(X - R_D) + W(X - R) \right]
\]  
(19)

However, after the initial drop, \( \Pi_{s>s^W}^B \) may start increasing in \( s \).

Consider the derivative of \( \Pi_{Liq}^B \):

\[
\frac{d\Pi_{Liq}^B}{ds} = \frac{dm_{Liq}^W}{ds}p(1 - \theta)(1 - p) \left[ D(X - R_D) + W(X - R_{Liq}) \right] - \frac{dR_{Liq}}{ds} \left[ p - (1 - m_{Liq}^W)p(1 - \theta)(1 - p) \right] W
\]  
(20)

The first term on the right-hand side represents the impact of higher seniority on
monitoring and is negative, \( dm_{\text{Liq}}/ds < 0 \), since with higher \( s \) the wholesale financier monitors the bank less, resulting in more inefficient liquidations. However, the second term is positive, \( dR_{\text{Liq}}/ds < 0 \), since with higher \( s \) the bank pays a lower interest rate on wholesale funding (the wholesale financier is compensated more in early liquidations instead). Therefore, the overall effect of higher \( s \) on \( \Pi_{\text{Liq}}^B \) is ambiguous.

The full analytical examination of \( \Pi_{\text{Liq}}^B \) is complicated by the fact that its convexity depends on the shape of \( C(m) \), including the third derivative. Since the shape of \( C(m) \) is not at the core of our argument, we make a simplifying restriction to focus the exposition on the other effects that we want to highlight. Specifically, we consider a very well-behaved \( C(m) \), such that \( m \) is effectively constant, \( m = m_C \), in the relevant range of parameter values. This corresponds to \( C(m) \) having a sharp J-shape that is almost horizontal until \( m_C \) and almost vertical after that. Figure 2 depicts possible shapes of \( \Pi_{\text{Liq}}^B \) that are allowed or ruled out by this simplification, to help us understand the dimensions of generality we are preserving or losing.

The key impact of the restriction is that the first term in (20) becomes zero, while the second term becomes a constant. We therefore are left with a linear and increasing \( \Pi_{\text{Liq}}^B \), and the global maximum of \( \Pi^B \) is achieved in either \( s = s^W \) when \( \Delta \Pi^B = \Pi_{\text{Liq},s=1}^B - \Pi_{s=s^W}^B \) is positive, or \( s = 1 \) otherwise. From (17) and (18),

\[
\Delta \Pi^B = p [R_{s=s^W} - R_{\text{Liq},s=1}] W - (1-m_C) p (1-\theta) (1-p) [D(X - R_D) + W(X - R_{\text{Liq},s=1})]
\]

The first term reflects a lower interest expense for more senior wholesale funds, in the case of project success. The second term reflects the probability of inefficient liquidations.

We examine cross-sectional properties of \( \Delta \Pi^B \) with respect to three key parameters of the model: \( \theta, L, D, \) and \( W \), and summarize the findings in Lemma 3:

**Lemma 3** \( \Delta \Pi^B \) increases in \( \theta \) and \( L \); it increases in \( D \) and decreases in \( W \).

**Proof.** See Appendix. \( \blacksquare \)

The intuition is that, higher \( \theta \), \( L \), and \( D \) reduce the cost of early liquidations for
the wholesale financier, which translates into lower interest rate charged by him and accordingly higher surplus for the bank.

We then conduct a simple numerical exercise, to demonstrate how, within a plausible range of parameter values, \( \Delta \Pi^B \) can be either positive or negative, validating the existence of both bright and dark sides of wholesale funding. The outcome of the exercise is illustrated in Figure 3.\(^3\)

Based on Lemma 3 and the numerical analysis, we can now summarize in Proposition 3 the bank’s incentives of assigning too high seniority to wholesale funds despite the risk of inefficient liquidations:

**Proposition 3** The "dark side" of wholesale funding exists: the set of parameter values for which the bank assigns the wholesale financier too high seniority, subjecting itself to the risk of inefficient liquidations, is non-empty. All else equal, the bank has higher incentives to assign too high seniority to the wholesale financier when the precision of the public signal \( \theta \) is higher, the liquidation value \( L \) is higher, and there are more deposits \( D \) serving as buffer for short-term funds’ exit.

4 Discussion

This section discusses some features of our model and briefly outlines policy insights.

**Comparative statics** Propositions 2 and 3 offer cross-sectional predictions on the risk of inefficient liquidations in different types of banks. They identify that banks are more likely to assign too high seniority to wholesale funds, while senior wholesale financiers are more likely to subject banks to inefficient liquidations, when the precision of the public noisy signal on bank project quality \( \theta \) and the bank’s liquidation value \( L \) are higher. These two predictions suggest a distinction between "traditional" banks that

---

\(^3\)The simulation is based on the following parameter values: \( m = 0.5, \rho = 1, \rho = 0.90, X = 1.15, R_D = 1.10 \). \( W \) takes the values of 0.25, 0.5, and 0.75, respectively, in three different scenarios. We have considered alternative specifications, and confirmed that the properties revealed by the figures are robust to choosing other parameter values.
hold primarily relationship-based small business loans (associated with low $\theta$ and $L$) and "modern" banks that hold more tradable and arm’s length assets such as mortgage loans or securities (associated with higher $\theta$ and $L$). The "bright side" of wholesale funding – beneficial monitoring and market discipline – is likely to dominate in traditional banks, consistent with the original CK predictions. Yet the modern banks are likely affected by the "dark side" of wholesale funding.

**Long-term funds and non-depository banks** The model identifies long-term bank funding with "retail deposits" that are effectively passive (never withdrawn at an intermediate date) and risk-insensitive (possibly due to deposit insurance). It is important to point out, however, that "retail deposits" in our model can be taken as a metaphor for all long-term funds (such as bonds or customer funds) that would likely lose out to short-term wholesale funds when scrambling for the liquidated assets. Consequently, our model can be taken to describe a broader conflict of interest between short-term and long-term bank financiers in non-bank financial institutions that may have no insured retail deposits whatsoever.

For example, the run on Bear Stearns (BSC) could be linked to the conflict of interest between short-term collateralized funds (such as repo’s) and long-term funds (including funds due to customers, and long-term borrowings), which accounted for about 42 percent of BSC’s total liabilities. The short-term financiers withdrew, rapidly reducing BSC’s pool of high-quality, highly liquid assets from $18.1 billion on March 10, 2008, to $2 billion on March 13.

**Policy implications** In our model, the bank’s suboptimal use of senior wholesale funds is driven by its private benefits of interest expense savings. A Pigouvian tax on senior wholesale funds, similar to that proposed in Perotti and Suarez (2009), may help align the bank’s incentives with the social optimum. In practice, that would likely correspond to taxing the use of short-term wholesale funds such as collateralized repo’s, because short maturity and collateral are good proxies for effective seniority.
This tax shares intuition with the systemic risk tax proposed in Acharya et al. (2010), in that both attempt to cause banks to internalize the negative externality that their actions impose on the rest of the financial system. The proposal of Acharya et al. (2010) targets not just one risk factor but overall systemic risk and is therefore more comprehensive and able to capture future sources of vulnerability.

5 Conclusion

Our paper identifies and analyzes the "dark side" of bank wholesale funding – the scope for opportunistic behavior by short-term wholesale financiers (i.e., insufficient monitoring and abrupt withdrawals based on noisy public information) and by banks (i.e., using such risky wholesale funds and assigning them too high creditor seniority). In a bank cross-section, the model predicts that wholesale funds can be safely and indeed beneficially used in "traditional" banks that make opaque and non-tradable relationship loans. In contrast, short-term wholesale funds can create significant risks in "modern" banks that hold arm’s length assets with readily available, but noisy, public signals on fundamentals.
A Proofs

Lemma 1  Recall that:

\[ H^B = p[D(X - R_D) + W(X - R)] \]
\[ R = \frac{Wp + C(m^W) - m^W(1 - p)sL(D + W)}{Wp} \]

1a. Consider \(d\Pi^B/ds\). Observe:

\[
\frac{d\Pi^B}{ds} = -Wp\frac{dR}{ds} = -\left[ \frac{dC(m^W)}{ds} - \frac{dm^W}{ds}(1 - p)sL(D + W) - m^W(1 - p)L(D + W) \right]
\]

Since:

\[
\frac{dC(m^W)}{dm^W} = (1 - p)sL(D + W)
\]

We have:

\[
\frac{dC(m^W)}{ds} = \frac{dm^W}{ds}(1 - p)sL(D + W)
\]

Substituting gives:

\[
\frac{d\Pi^B}{ds} = -\left[ \frac{dm^W}{ds}(1 - p)sL(D + W) - \frac{dm^W}{ds}(1 - p)sL(D + W) - m^W(1 - p)L(D + W) \right] = m^W(1 - p)L(D + W) > 0
\]
1b. Now consider $d\Pi^B/dW$. Observe:

$$
\frac{d\Pi^B}{dW} = p (X - R) - Wp \frac{dR}{dW}
$$

Solving $dR/dW$ and using similar substitution as above gives:

$$
\frac{d\Pi^B}{dW} = p (X - R) - Wp \left[ \frac{-m^W (1 - p)sL \cdot Wp - p \cdot [W \rho + C(m^W) - m^W (1 - p)sL(D + W)]}{W^2p^2} \right] > 0
$$

1c. Therefore $\Pi^B$ is increasing in $s$ and $W$ and is maximized for $s = 1$ and $W = 1 - D$.

QED

**Lemma 2** Recall:

$$
S^W = \frac{(1 - \theta)pWR}{L(D + W)}
$$

2.1a. see immediately that:

$$
\frac{ds^W}{d\theta} = - \frac{pWR}{L(D + W)} < 0
$$

2.1b. Consider $ds^W/dL$. Substitute $R$:

$$
\frac{ds^W}{dL} = d \left( \frac{1 - \theta}{L} \right) W \rho + C(m^W) - m^W (1 - p)sL(D + W) \right) \right) \frac{L(D + W)}{L^2(D + W)}
$$

Recalling from proof of Lemma 1 that:
\[ \frac{dC(m^W)}{dL} = \frac{dm^W}{dL} (1 - p)sL(D + W) \]

Gives:

\[ \frac{ds^W}{dL} = (1 - \theta) \frac{-m^W(1 - p)sL(D + W) - [W\rho + C(m^W) - m^W(1 - p)sL(D + W)]}{L^2(D + W)} < 0 \]

2.1c. Consider \( ds^W/dD \). Observe that the numerator of \( s^W \) decreases in \( D \) since \( dR/dD < 0 \) while the denominator increases in \( D \). Therefore, \( s^W \) decreases in \( D \):

\( ds^W/dD < 0 \).

2.1d. Consider \( ds^W/dW \) under \( D + W = 1 \). Substitute \( R \):

\[ \frac{ds^W}{dW} = \frac{(1 - \theta)}{L} \cdot \frac{d}{dR} [W\rho + C(m^W) - m^W(1 - p)sL(D + W)] \]

Solving and substituting similarly to above gives:

\[ \frac{ds^W}{dW} = \frac{(1 - \theta)}{L} [\rho - m^W(1 - p)sL] > 0 \]

2.2-2.3. These were explained in text.

2.4. Consider the switch between \( m^W \) and \( m^W_{Liq} \) and between \( R \) and \( R^W_{Liq} \). We seek to show that these are continuous at \( s^W \).

Observe that:
\[ C'(m_{s=s}^W) = (1 - p)s^W L(D + W) \]
\[ = p(1 - p)(1 - \theta)WR \]

and:

\[ R_{s=s}^w = \frac{WP + C(m_{s=s}^W) - m_{s=s}^W (1 - p)(1 - \theta) WP R_{s=s}^w}{WP} \]
\[ = \frac{WP + C(m_{s=s}^W)}{WP [1 + m_{s=s}^W (1 - p)(1 - \theta)]} \]

Similarly,

\[ C'(m_{\text{Liq},s=s}^W) = p(1 - p)(1 - \theta)WR_{\text{Liq},s=s}^w \]

and:

\[ R_{\text{Liq},s=s}^w = \frac{WP + C(m_{\text{Liq},s=s}^W) - m_{\text{Liq},s=s}^W (1 - p)(1 - \theta) WP R_{\text{Liq},s=s}^w}{m_{\text{Liq},s=s}^W WP + (1 - m_{\text{Liq},s=s}^W) [p + \theta(1 - p)] WP} \]
\[ = \frac{WP + C(m_{\text{Liq},s=s}^W)}{WP [1 + m_{\text{Liq},s=s}^W (1 - p)(1 - \theta)]} \]

It is evident that the two systems, the first of which defines \( \{m_{s=s}^W; R_{s=s}^w\} \) and another \( \{m_{\text{Liq},s=s}^W; R_{\text{Liq},s=s}^w\} \), are identical.

QED

**Lemma 3** Consider \( \Delta \Pi^B \); recall we established that a bank always chooses \( W = 1 - D \), so that:

\[ \Delta \Pi^B = pW [R_{s=s}^w - R_{\text{Liq},s=1}] - (1-m_C)p(1-\theta)(1-p) [(1 - W)(X - R_D) + W(X - R_{\text{Liq},s=1})] \]
Substitute expressions for $R_{s=W}$ and $R_{Liq,s=1}$ (using $m = m_C$ and $C(m_C) = 0$):

$$
R_{s=W} = \frac{W\rho}{Wp (1 + m_C(1 - p) (1 - \theta))}
$$
$$
R_{Liq,s=1} = \frac{W\rho + C(m_C) - (1 - p)L}{Wp |m_C + (1 - m_C) [p + \theta(1 - p)]|}
$$

to obtain:

$$
\Delta \Pi^B = \left[ \frac{W\rho}{1 + m_C(1 - p) (1 - \theta)} - \frac{W\rho - (1 - p)L}{m_C + (1 - m_C) [p + \theta(1 - p)]]} - (1 - m_C)p(1 - \theta)(1 - p) \left[ X - (1 - W)R_D - W \frac{W\rho - (1 - p)L}{Wp |m_C + (1 - m_C) [p + \theta(1 - p)]|}\right]\right]
$$

We can now establish the signs of the first derivatives.

3a. Note immediately that $d\Delta \Pi^B/dL > 0$

3b. Note that the first term of $\Delta \Pi^B$ increases in $\theta$: $R_{s=W}$ increases in $\theta$ while $R_{Liq,s=1}$ decreases in $\theta$.

In the second term, the first multiplier (probability of incorrect liquidation) decreases in $\theta$, while the second multiplier (surplus lost in incorrect liquidations) increases because $R_{Liq,s=1}$ declines. Yet the first effect dominates, so that the second term increases in $\theta$:

$$
\frac{d}{d\theta} \left[ (1 - m_C)p(1 - \theta)(1 - p) \left[ \frac{W\rho - (1 - p)L}{Wp |m_C + (1 - m_C) [p + \theta(1 - p)]|}\right]\right]
= \frac{[W\rho - (1 - p)L] (1 - m_C)(1 - p)}{|m_C + (1 - m_C) [p + \theta(1 - p)]|^2} > 0
$$

Therefore both terms increase in $\theta$ and $d\Delta \Pi/d\theta > 0$.

3c-d. We examine $d\Delta \Pi^B/dW$; $d\Delta \Pi^B/dD$ is inverse since a bank chooses $W = 1 - D$. 

26
The first term of $\Delta \Pi^B$ decreases in $W$:

$$
\frac{d}{dW} \left[ \frac{W \rho}{1 + m_C(1-p)(1-\theta)} - \frac{W \rho - (1-p)\xi}{m_C + (1-m_C) [p + \theta(1-p)]} \right] \\
= -\rho \frac{(1-p)(1-\theta)(1 + m_C(1-p)[p + \theta(1-p)])}{(1 + m_C(1-p)(1-\theta))(1 + m_C(1-p)\xi)} < 0
$$

In the second term, two factors affect the bank’s loss in incorrect liquidations. First, $R_{Liq}$ decreases in $W$ and therefore increases the bank’s surplus. Second, the shift from depository funding at cost $R_D$ to wholesale funding at cost $R_{Liq}$ increases the bank’s surplus for $R_D > R_{Liq}$ or reduces it for $R_D < R_{Liq}$.

However, overall, the effects stemming from the first term dominate, and $d\Delta \Pi/dW < 0$. Indeed, consider:

$$
\frac{d\Delta \Pi^B}{dW} = \frac{\rho}{1 + m_C(1-p)(1-\theta)} - \frac{\rho}{m_C + (1-m_C) [p + \theta(1-p)]} \\
-\frac{(1-m_C)(1-\theta)(1-p) \rho [m_C + (1-m_C) [p + \theta(1-p)]]}{[m_C + (1-m_C) [p + \theta(1-p)]] [m_C + (1-m_C) [p + \theta(1-p)]]} R_D - \rho \\
= \frac{(1-p)(1-\theta)(1 + m_C(1-p) [p + \theta(1-p)])}{[m_C + (1-m_C) [p + \theta(1-p)]] [m_C + (1-m_C) [p + \theta(1-p)]]} R_D - \rho
$$

Now arrange the fraction and consider solely the numerator (the denominator is positive):

$$
\rho [m_C + (1-m_C) [p + \theta(1-p)]] - \rho [1 + m_C(1-p)(1-\theta)] + \rho(1-m_C)(1-\theta)(1-p) [1 + m_C(1-p)(1-\theta)] - \xi R_D
$$

Where $\xi$ is a positive coefficient. Arranging the terms yields:
\[ \rho(1 - p)(1 - \theta)(1 - m_C) \left([1 + m_C(1 - p)(1 - \theta)] - 1\right) - \xi R_D \]
\[ < \rho(1 - p)(1 - \theta)(1 - \frac{m_C^2}{1}) - \xi R_D \]
\[ = -m_C^2\rho(1 - p)(1 - \theta) - \xi R_D < 0 \]

Therefore \(d\Delta \Pi^B/dW < 0\) and \(d\Delta \Pi^B/dD > 0\).

QED

Figure 1.

The wholesale financier’s monitoring and liquidation decisions.

The left panel illustrates the benchmark case without a noisy public signal: the wholesale financier’s intensity of monitoring $m$ increases monotonically in his creditor seniority $s$. The right panel depicts the case with a noisy signal. There, when seniority exceeds the threshold value $s=s^W$, the wholesale financier starts to reduce his intensity of monitoring in response to higher seniority.

**Without a noisy signal**

```
\[ m \quad m^* \quad s \quad 1 \]
```

**With a noisy signal**

```
\[ m \quad m^* \quad s^W \quad 1 \quad s \]
```

No inefficient liquidations | Liquidations upon a noisy negative signal
Figure 2.

The bank’s surplus depending on the wholesale financier’s seniority

The figures depict a bank's surplus $\Pi^B$ as a function of the wholesale financier’s creditor seniority $s$. The left panel shows the bank's surplus in the benchmark case without a noisy signal. The right panel shows the case with the noisy signal. There, the continuous lines and the shaded area between them represent shapes complying with the $m=m_C$ assumption (all linear), while the broken lines represent examples of shapes ruled out by that assumption. The point $s^W$ is the threshold beyond which the wholesale financier liquidates a bank based on a negative public signal.
Figure 3.

The bright and dark sides of bank wholesale funding.

Line 1 represents pairs of signal precision $\theta$ and liquidation value $L$ that satisfy $\Delta \Pi^B = 0$. All points below that line satisfy $\Delta \Pi^B \geq 0$ so that the bank has the incentive to assign socially optimal seniority $s^W$ to wholesale funds: the “bright side” of wholesale funding. All points above that line satisfy $\Delta \Pi^B < 0$ so that the bank has the incentive to assign too high seniority $s=1$ to wholesale funds: the "dark side" of wholesale funding.

The other lines represent additional parameter restrictions used in the model. Line 2 is $\theta > \theta^W_{s=1}$ (existence of inefficient liquidations; indistinguishable from line 1 in the middle graph). Line 3 is $\theta < \theta^*$ (early liquidations based on noisy signals are not socially optimal). Line 4 is a tractability restriction $p^W > L$, corresponding to non-negligible wholesale funding.
